ABSTRACT

Mango is heterozygous in nature and exhibits great diversity in seedling population. In order to broaden the genetic base, a survey of mango growing regions of Punjab (India) was made and more than 60 sucking mango strains were collected. The performance of twenty-six elite sucking mango strains was assessed in terms of vegetative growth, fruit yield and quality attributes. Maximum tree vigour was recorded in GN₉. All the strains were severely infested by floral malformation except in GN₃, GN₉, GN₂₁, GN₂₂, GN₂₆, GN₃₅ and GN₄₈, where it was less than 5 per cent. Fruit yield ranged between 47.5 kg/tree in GN₁₆ to 178.8 kg/tree in GN₆. GN₈ strain had bigger fruit weight and fruit length, whereas; highest peel weight, stone weight and fruit breadth was found in GN₆. The highest fruit pulp percentage was observed in GN₁₃ and it ranged from 41.9% to 65.7% in rest of strains. Lower fruit length and breadth was noted in GN₁ (5.57 cm) & GN₄₈ (4.46 cm), respectively. Total soluble solids in various strains varied from 13.2 (GN₁₈) to 22.9 per cent (GN₄₉), acidity from 0.32 (GN₄₉) to 0.61 per cent (GN₂₁) and TSS/acid ratio from 23.8 (GN₆) to 71.6 (GN₄₉). The fibre content was absent in GN₁, GN₅, GN₈, GN₁₀, GN₁₆ & GN₁₈. Fruit colour was sindhuri yellow in GN₂, GN₅, GN₆, GN₁₅, GN₁₇ and GN₂₁. Strains GN₃, GN₅, GN₆, GN₁₂, GN₁₅, GN₁₉ and GN₄₈ were found to be promising under Punjab agro-climatic conditions.

Key Words: Genetic variability, germplasm, *Mangifera indica* L.

INTRODUCTION

Mango (*Mangifera indica* L.) known as 'king of fruits', occupies an important position in the fruit industry of India. It has a growth history of at least 4000 years in the Indian sub-continent. The genus '*Mangifera*' originated in South-Eastern Asia belongs to family 'Anacardiaceae' and comprises sixty-nine species (Kostermans and Bompard, 1993). India has the world's largest mango germplasm, where more than one thousand vegetatively propagated varieties or wild types are cultivated (Bal, 2003). Majority of these have been selected as superior chance seedlings arisen from open cross-pollination. Since, time immemorial, propagation of mango was done through seeds. Hence, a large population of old mango seedlings is found growing in different parts of the country. These seedlings have shown wide genetic diversity in terms of fruit size, shape, colour, flavour, taste, time of maturity, fruit yield, bearing regularity,

resistance to malformation and other maladies (Singh and Sharma, 2005). Due to long history of cultivation in the country, mangoes are also known for sucking qualities. They possess ideal physico-chemical attributes like oblong shape, unrupturable skin, thin & abundant juice, scanty fibres, small stone, superior TSS/acid blend & flavour etc. Several workers have described the promising local mango seedlings under different agro-climatic conditions (Teotia and Singh, 1963; Sharma et al., 1984; Dhillon et al., 2001) In Punjab (India), mango cultivation is practically confined to sub-mountane zone including *kandi* areas. These regions are famous for sucking type mangoes and exhibit a wide genetic variability. Hence, mango-growing regions of the Punjab state were surveyed in early seventies, to harness the natural unrecorded variability. As a result, more than sixty sucking type strains possessing desirable horticultural traits were collected and planted at Fruit Research Station, Gangian for their maintenance, conservation and as a build-up material for future breeding programmes. These strains were coded as GN₁ to GN₆₀. Importance of germplasm in crop improvement is well recognized, therefore, present study has been undertaken to discuss various vegetative and quality attributes for different sucking mango strains under sub-mountane conditions of Punjab.

MATERIALS AND METHODS

The investigations were carried-out at Punjab Agricultural University, Fruit Research Station, Gangian (Dasuya) Hoshiarpur. The experimental site was situated in the sub-mountane zone of Punjab (India) between latitude of 31⁰N and longitude of 75⁰E at an elevation of 248.9 m above the mean sea level. Twenty-six elite-sucking type mango strains having vigorous tree growth and uniform age of 28 years were selected for the evaluation of their performance during 2004-05. The plants were given uniform cultural practices during the course of studies. The vegetative growth parameters were recorded in the month of October after the growth cessation. Stem girth was estimated with measuring tape from the marked places at 15 cm height from the bud union. Tree height and spread (mean of North-South and East-West) was noted with meter rod. Fruit yield was recorded in kg/tree by counting and multiplying the number of fruits with average fruit weight. The floral malformation was noted in the month of April by counting the infected panicles and percentage was worked out from total number of panicles on the tree. The observations on fruit size, peel weight, stone weight, pulp per cent, pulp/stone ratio, fruit colour, flavour and time of maturity were recorded as per standard procedure. The juice was extracted from the pulp by straining through a muslin cloth and total soluble solids were noted with Bausch and Lomb hand refractometer in term of degree Brix (%) and values were corrected at 20⁰C. Acidity was estimated by titration of known volume of juice against N/10 NaOH using phenolphthalein as an indicator.

RESULTS AND DISCUSSION

Tree characters, floral malformation and fruit yield

The results indicate (Table I) that the strain GN₉ was found to be most vigorous which recorded highest stem girth (196 cm); tree spread (11.75 m) and tree height (12.30 m). However, minimum stem girth, tree spread and height were found in GN₁₁ (103.5 cm), GN₄₉ (6.25 m) and GN₄ (7.78 m), respectively. Dhillon et al. (2001) also reported similar type of observations in respect to growth parameters in different sucking type mango selections. The lowest incidence of floral malformation was noted in GN₂₁ (2.8%) followed by GN₃ (3.0%), GN₃₅ (3.2%), GN₂₆ & GN₄₈ (3.5%), GN₉ (4.0%) and GN₂₂ (4.5%). Maximum occurrence of this malady was observed in GN₁₃ (19.6%), conversely, in other strains, it ranged from 5.2 per cent in GN₂₃ to 18.2 per cent in GN₈. Wide variability in mango malformation exists, which can be exploited to identify the resistance in strains for future breeding programme. The highest average fruit yield of 178.4 kg was noted in GN₆. The second largest fruit yield of 171.5 kg was observed in GN₃, followed by GN₁₉. Strain-GN₁₆ was the lowest (47.5 kg) fruit yielder. Similar type of variability in different

mango selections/varieties was also noted by many workers (Katrodia et al., 1989; Dhillon et al., 2001).

Fruit characters

The fruit weight also varied greatly in different strains (Table I) with maximum in GN₈ (220.2 g) and minimum (69.0 g) in GN₂₃. However, strains-GN₆, GN₁₉, GN₁₂ & GN₁₃ had fruit weight of 211.8, 188.0, 175.5 & 172.3 g, respectively. The highest peel and stone weight to the tune of 45.7 and 47.6 g, respectively was noted in GN₆ (Table II). The smallest stone with an average weight of 18.9 g was found in GN₁₀. Peel weight of the fruit was observed to be minimum (11.3 g) in GN₁. The average pulp/stone ratio in different strains varied from 1.32 to 3.85, being maximum in GN₁₃ and minimum in GN₁₇. The highest pulp percentage of 66.9 was found in GN₁₃, closely followed by 65.7 in GN₁₈ and 65.6 in GN₈. In remaining strains, it ranged from 41.9% to 63.3%, being lowest in GN₂₃. GN₈ recorded highest (10.61 cm) fruit length, followed by GN₁₂ and GN₁₃, while lowest (5.57 cm) in GN₁. On the other hand, GN₆ had maximum (7.90 cm) fruit breadth and it was minimum (4.46 cm) in GN₄₈. Kulkarni and Rameshwar (1981) and Parida and Rao (1989) reported variation in fruit characters in different strains/cultivars of mango under agro-climatic conditions of Andhra Pradesh and Orissa, respectively.

Fruits with uniform and oblong shape fetch higher market price and considered good for processing. On the basis of fruit shape, strains are classified as ovate (GN₁, GN₃, GN₅, GN₁₁, GN₂₂, GN₂₃, GN₂₆ & GN₄₉), oblong (GN₆, GN₇, GN₈, GN₁₂, GN₁₃, GN₁₅, GN₁₆, GN₃₄ & GN₄₈) and ovate oblong (GN₂, GN₄, GN₉, GN₁₀, GN₁₇, GN₁₈, GN₁₉, GN₂₁ & GN₃₅). Mukherjee et al. (1983) also classified mango varieties into three categories under West Bengal conditions. Fruit colour in most of strains was light green, greenish yellow, light yellow, yellowish green, yellow and pale yellow (Table III). Strains viz. GN₂, GN₅, GN₆, GN₁₅, GN₁₇ & GN₂₁ had bright, attractive yellow colour with red or sindhuri blush on their fruit skin. These can be used as a donor source for developing coloured mango hybrid cultivars. Singh and Jawanda (1963) reported similar observations in term of fruit skin colour in different sucking type mango strains.

Wide variability was recorded for the presence of flavour and aroma in fruits at the time of ripening, which is one of the most important characters for identifying sucking type mango strains. In present study, fruits of strains i.e. GN₂, GN₃, GN₆, GN₁₂, GN₁₉ & GN₄₈ had excellent taste, aroma and flavour. Fibres on the stone were absent in GN₁, GN₅, GN₈, GN₁₀, GN₁₆ & GN₁₈, while all other strains were less or more fibrous. The fruit maturity in sucking type of mango has been classified as Early (Ist week of July), Mid (IInd & IIIrd week of July) and Late (beyond IVth week of July).

Chemical characters

Chemical quality attributes among the different strains also depicted genetic variability (Table III). Juice extracted from fruit pulp of different strains-GN₁₀, GN₁₅, GN₂₃ and GN₄₉ contained more than 20 per cent total soluble solids content, though, the least to the tune of 13.2 per cent was observed in GN₁₈. Important sucking type mango strains grown under Uttar Pradesh state conditions have also shown variability in soluble solids from 13.5 to 18.2 per cent (Rabbani and Singh, 1989). The highest (0.61%) fruit acidity was noted in GN₂₁ and this content varied from 0.53 to 0.60 percent in GN₁₅, GN₁₂, GN₃₅, GN₂₂, GN₄, GN₉ and GN₆. On the other hand, the lowest (0.32%) acidity was recorded in GN₄₉. Dhillon et al. (2001) also reported higher fruit acid content in sucking type mangoes; therefore, some strains can be selected for pickle purposes on the basis of other desirable characters. As far as TSS/acid ratio is concerned, the maximum (71.6) was found in GN₄₉ and the minimum (23.8) in GN₆.

CONCLUSION

Based on overall performance with respect to vegetative, maturity period, fruiting and physico-chemical attributes, strains GN₃, GN₅, GN₆, GN₁₂, GN₁₅, GN₁₉, and GN₄₈ have been found promising for sucking type of mangoes under sub-montane conditions of Punjab.
